

**Research Summary – Wingate Anaerobic Test (WAnT) – Other**

<b>Author Year Country Research Design Setting</b>	<b>Demographics and Injury Characteristics of Sample</b>	<b>Validity</b>	<b>Reliability</b>	<b>Responsiveness Interpretability</b>
<p><a href="#">Nash et al. (2007)</a></p> <p>Repeated Testing</p> <p>Academic medical centre.</p>	<p>7 participants with motor-complete (AIS A or B) paraplegia Age range: 39-58 yrs old DOI: 13.1±6.6 yrs</p> <p>T5-T12 injuries</p> <p>Study participants recruited from a pool of volunteers who reported mild to moderate upper limb pain during the performance of daily activities and used a manual wheelchair for locomotion. All participants had been physically inactive for at least 6 months before entry into the study.</p>			<p><b>Interpretability:</b> Subjects underwent circuit resistance training (CRT) 3 times weekly on nonconsecutive days for 16 weeks. Each session lasted approximately 40-45 minutes and included resistance training and high-speed, low-intensity endurance activities (arm cranking) with interposed periods of incomplete recovery (heart rate not falling to baseline). Effects of CRT on anaerobic power: (values are mean (SD))</p> <p>See table 1 below.</p>

Author Year Country Research Design Setting	Demographics and Injury Characteristics of Sample	Validity	Reliability	Responsiveness Interpretability															
<p>After 12 weeks of training, both study groups (ET and RT) displayed significant increases in Ppeak and Pmean (P&lt;0.05). Mean power increased 8% and 5% for the RT and ET groups, respectively, with no statistically significant differences apparent between groups. Whereas RT and ET both produced significant enhancement of Ppeak (P&lt;0.05), the RT produced significantly greater gains (15.6%) compared with ET (2.6%).</p>
