acceptable.

Inter-rater reliability coefficient (R):

Muscle	Average R	Single-trial R
Left biceps	0.36	0.22
Right biceps	0.21	0.11
Left triceps	0.89	0.80
Right triceps	0.74	0.59
Left wrist extensors	0.84	0.73
Right wrist extensors	0.84	0.72

Burns et al. 2005

No data available

For both make and break techniques, strength measurements showed high reliability for both interrater and intrarater reliability comparisons.

	ICC:	95% confidence interval:
<b>Intra-rater reliability:</b>	--	--
Examiner 1 make	0.91	0.79-0.97
Examiner 2 make	0.94	0.86-0.98
Examiner 1 break	0.94	0.86-0.98
Examiner 2 break	0.93	0.82-0.97
<b>Inter-rater reliability:</b>	--	--
Examiner 1 make	0.94	0.86-0.98
Examiner 2 make	0.97	0.93-0.99
Examiner 1 break	0.95	0.87-0.98
Examiner 2 break	0.94	0.86-0.98

For these intra-rater comparisons, the mean difference in strength between the two sessions averaged between 1.0 and 1.5 kg. Within-participant standard deviation for the intrarater comparisons ranged from 0.8 to 1.3 kg, with no significant difference between make and break technique. The corresponding range for repeatability, 2.5-3.5 kg, indicates the maximum expected difference between two repeated measurements for 95% of paired observations. Within-participant standard deviation for the inter-rater comparisons ranged from 0.9 to 1.1 kg, with repeatability of between 2.6 and 2.9 kg, and there was no significant differences between repeatability for make and break techniques. Plots of differences between strength measurements for intra-rater and inter-rater comparisons showed no evidence of improved agreement later in the study, after the examiners gained experience with HHD.

May et al. 1997

No data available

*Break test repeated three times for internal and external rotation on right and left shoulder. (All testing completed in one session.)*

**Intra-rater reliability assessed with ICC. Brackets indicate 95% confidence interval.**  
 External rotation: all ICC=0.94 (.91-.96), paraplegics ICC=.89 (.80-.94), tetraplegics ICC=.93 (.86-.96)  
 Internal rotation: all ICC=.96 (.94-.98), paraplegics ICC=.92 (.86-.96), tetraplegics ICC=.89 (.81-.94)

Lamontagne et al. 1998

No data available

*Resistive torque upon stretch of the plantar flexors was measured using a hand-held dynamometer (HHD) or a Kin-Com Isokinetic Dynamometer (ID). Ankle stretch was performed at set high (180°/s) or low (5°/s) velocities (this was estimated manually with the HHD).*

		<p><b>Intraclass correlation coefficients.</b></p> <p><u>HHD:</u> ICC<math>\bar{s}</math> for movements at low velocity were similar whether all trials were included (n=5; ICC=0.93) or the first trial was excluded (n=4; ICC=0.94). ICC<math>\bar{s}</math> for movements at high velocity were also similar when all trials were included (ICC=0.84) or the first trial was excluded (ICC=0.81), but were lower than low velocity ICC<math>\bar{s}</math>.</p> <p><u>ID:</u> ICC<math>\bar{s}</math> were higher when the first trial was excluded (low velocity: ICC=0.99; high velocity: ICC=0.93) compared to when it was included (low velocity: ICC=0.83; high velocity: ICC=0.75). Similar to HHD, ICC<math>\bar{s}</math> were lower for the high velocity movements.</p> <p><b>Intertrial variability was expressed with Coefficients of variation (as a percentage) using the last four trials.</b></p> <p>CV<math>\bar{s}</math> were generally higher for the HHD method compared to the ID method.</p> <p>Resistive torque: Low velocity CV=7.98 (HHD) and CV=3.14 (ID) High velocity CV=16.11 (HHD) and CV=6.43 (ID)</p> <p>Velocity: Low velocity CV=40.43 (HHD) and CV=7.84 (ID) High velocity CV=12.74 (HHD) and CV=0.47 (ID)</p>
Jacquemin 2004	No data available	<p><i>Bilateral measurements were made by two testers, three times each for each of the muscle groups (second digit abductors, fifth digit abductors and thumb opposers).</i></p> <p><b>Bland-Altman plotting method.</b> Inter-rater differences varied with the level of strength (more variance at higher strength), but differences relative to strength were similar except at strength levels below 1.0kg. Values below 1.0kg were excluded for 95% interval calculation.</p> <p>The mean of the highest of 2 of 3 trials was used to define the upper limit (95<sup>th</sup> percentile) of normal inter-rater differences with 29.3, 38.5 and 43.7% for second digit abductor (2<sup>nd</sup> abd), fifth digit abductor (5<sup>th</sup> abd) and thumb opposition (1<sup>st</sup> opp), respectively. This study suggests that serial strength differences exceeding these values are likely to represent significant changes in muscle strength.</p> <p>95<sup>th</sup> Percentile of Interraters differences Max strength: 35.8 (2<sup>nd</sup> adb), 40.0 (5<sup>th</sup> abd), 43.7 (1<sup>st</sup> opp) Mean of 2 highest: 29.6 (2<sup>nd</sup> adb), 38.5 (5<sup>th</sup> abd), 43.7 (1<sup>st</sup> opp) Mean of 3: 29.3 (2<sup>nd</sup> adb), 35.0 (5<sup>th</sup> abd), 38.6 (1<sup>st</sup> opp) Median of 3: 31.9 (2<sup>nd</sup> adb), 40.0 (5<sup>th</sup> abd), 43.7 (1<sup>st</sup> opp)</p>
Herbison et al. 1996	No data available	Inter-rater reliability for myometer testing was 0.82.
Schwartz et al 1992	No data available	<p>Sequential motor strength examination using both MMT and hand-held myometry were performed at 72 hours, 1 and 2 weeks and 1, 2, 3, 4, 6, 12, 18 and 24 months post-injury.</p> <p>Inter-rater reliability for all muscles tested was r=0.94.</p>
<b>2. VALIDITY</b>		
<b>Author ID</b>		

May et al. 1997	<p><i>The averages of three HHD measurements were compared to the averages of four trials with an isokinetic dynamometer.</i></p> <p><b>Pearson correlation coefficient.</b> All correlations were significant (<math>P &lt; .0001</math> for whole group comparisons; <math>P &lt; .01</math> for groups by SCI type). External rotation: all <math>r = 0.86</math>, paraplegics <math>r = 0.83</math>, tetraplegics <math>r = 0.56</math> Internal rotation: all <math>r = 0.88</math>, paraplegics <math>r = 0.74</math>, tetraplegics <math>r = 0.52</math></p> <p>The Pearson product moment correlation as calculated for the combined data of all subjects was .88 for internal rotation and .86 for external rotation. Both correlations were significant at the <math>p &lt; .0001</math> level, indicating a good relationship between the HHD and Cybex measurements.</p> <p>Separate analyses of the paraplegia and tetraplegia data found significant correlations (<math>p &lt; .01</math>); however, the coefficients for the data of the persons with tetraplegia were considerably lower than those calculated for the persons with paraplegia.</p>
Jacquemin 2004	<p><i>Strength measurements compared to those obtained with Manual Muscle Test (MMT; graded scores from 0 to 5).</i></p> <p>Scores by these two methods were positively correlated, but were nonlinear with a marked dispersion of values at MMT grades 3, 4 and 5. This indicates a lack of sensitivity of the MMT method at those higher strength ranges, whereas myometry detected changes within this range.</p>
Herbison et al. 1996	<p><i>Hand held myometry (MYO) and manual muscle testing (MMT) were performed at various intervals between 72h to 2 years post-SCI. Groups were based on changes (half or full grade) from initial to later MMT score. For each interval, the later MYO measurement (MYO2) was divided by the earlier (MYO1). The result was multiplied by 100 to obtain a value which expressed the later strength of contraction as a percent of the earlier examination.</i></p> <p><b>Student t-tests were used to compare MYO1 and MYO2 values. Measures were expressed as geometric means (GM; MYO2/MYO1 x 100) and coefficients of variation of these % changes (CV).</b></p> <p>MYO was more sensitive than MMT in detecting strength changes. Values indicate (<u>GM-1 CV; GM; GM+1CV; significance level</u>).</p> <p>a) Two of the three groups that had no change in MMT scores had significant changes in MYO scores <input type="checkbox"/> MMT=4.0 (80; 140; 243; <math>p &lt; 0.05</math>), MMT=4.5 (84; 126; 187; <math>P &lt; .01</math>).</p> <p>b) There were also larger changes indicated by MYO for groups that made a half grade change in MMT scores <input type="checkbox"/> MMT=3.5-4.0 (123; 205; 342; <math>P &lt; .002</math>), MMT=4.0-4.5 (82; 139; 234; <math>P &lt; .02</math>) and MMT=4.5-5.0 (84; 126; 187; <math>P &lt; .02</math>).</p> <p>c) There were also larger changes indicated by MYO for groups that made a full grade change in MMT scores <input type="checkbox"/> MMT=3.5-4.5 (127; 232; 424; <math>P &lt; .05</math>) and MMT=4.0-5.0 (126; 191; 292; <math>P &lt; .001</math>).</p>
Noreau & Vachon 1998	<p><i>Measured elbow extension and flexion, shoulder extension and flexion, and shoulder adduction and abduction. The three tests were separated by at least one day and were all performed within a week.</i></p> <p><i>Manual muscle test (MMT) <input type="checkbox"/> graded from 0 to 5</i></p> <p><i>Hand-held myometer (HHM) <input type="checkbox"/> avg of three trials for each muscle group</i></p> <p><i>Isokinetic dynamometry (ID) - 60°/sec, tested stronger side of body</i></p> <p><b>Spearman correlations for comparison of MMT and HHM.</b> Paraplegics <math>r = 0.26-0.67</math> Tetraplegics <math>r = 0.50-0.95</math> Highest correlations were for elbow extension and shoulder flexion and adduction in tetraplegics at admittance (<math>r = 0.95, 0.83, 0.84</math>, respectively). The majority of correlations decreased at time of discharge.</p> <p>Spearman correlation coefficients between the strength values measured by MMT and myometry for six muscle</p>

groups (tested on both sides) in individuals with SCI (n=38):

Muscles:	Paraplegia (n=23)		Tetraplegia (n=15)	
	Admittance	Discharge	Admittance	Discharge
Elbow flexors	0.48	0.26**	0.58	0.48*
Elbow extensors	0.46	0.55	0.95	0.88
Shoulder flexors	0.63	0.60	0.83	0.50*
Shoulder extensors	0.44*	0.49	0.67	0.57
Shoulder abductors	0.64	0.57	0.55*	0.59
Shoulder adductors	0.67	0.34*	0.84	0.73

\*.001<P<.05

\*\*P=.084

P<=0.001 if not indicated

**Spearman correlations for comparison of MMT and ID.**

Paraplegics r=0.19-0.65

Tetraplegics r=0.35-0.95

**Pearson correlations for comparison of HHM and ID.**

Paraplegics r=0.70-0.90

Tetraplegics r=0.57-0.96

Lowest correlations were for elbow extension and shoulder abduction (paraplegics) and shoulder extension and abduction (tetraplegia). These correlations increased at discharge (as well as shoulder adduction in paraplegics).

Pearson correlation coefficients between the strength values measured by myometry and ID on 6 muscle groups (tested on stronger side) in individuals with SCI (n=38):

Muscles:	Paraplegia (n=22, missing one value)		Tetraplegia	
	Admittance	Discharge	Admittance	Discharge
Elbow flexors	0.76	0.75	0.81	0.75
Elbow extensors	0.70	0.82	0.92	0.96
Shoulder flexors	0.89	0.89	0.82	0.78
Shoulder extensors	0.85	0.83	0.59*	0.87
Shoulder abductors	0.73	0.82	0.57*	0.76
Shoulder adductors	0.81	0.90	0.91	0.90

Schwartz et al. 1992

Spearman rank correlation coefficients were performed looking at the MMT and myometry measurements.

Of the 24 correlation obtained between the two measures, 22 were significant (p<0.001). Correlations ranged from 0.59 to 0.94. The 2 non-significant correlations occurred at 12 months for the right biceps (r=.18) and left biceps (r=.42).

Spearman rank correlation between MMT and Myometry: time post SCI

Muscle:	72 hours	1 week	1 month	3 months	6 months	12 months
Left bicep	0.86	0.84	0.68	0.82	0.59	0.42
Right bicep	0.80	0.83	0.79	0.68	0.59	0.18
Left ECR	0.92	0.86	0.81	0.84	0.84	0.77
Right ECR	0.94	0.78	0.93	0.79	0.75	0.71

Correlation analysis found both modalities were measuring the strength of the muscle, but the myometry measured more subtle changes in muscle strength.

MMT data has a smaller increase from date of injury to 24 months post-injury, while myometry data reflect a steady increase in strength. This suggests that the MMT cannot detect small changes in strength. Schwartz proposes that this is because in order to receive a grade of 3.0 by the MMT method, only a small fraction of the motor neurons need to be functional while MMT strength grades above a 3.0 require activation of the majority of the remaining neurons.

Burns et al. 2005	<p>The break technique produced significantly greater strength measurements than did the make technique. We calculated this difference as the break/make (B/M) ratio. B/M ratios showed considerable variability between participants, and there was no significant difference in mean B/M ratios determined by the two examiners. For examiner 1, mean (SD) B/M was 1.41 (0.39) in session 1 and 1.48 (0.38) in session 2, with corresponding values of 1.38 (0.29) and 1.49 (0.37) for examiner 2. We found no association between the B/M ratio and either the DTR or MAS for the test muscle.</p>
